

What is a Small Solar System body? A small Solar System body is an object in the Solar System that is neither a planet, a dwarf planet, nor a natural satellite.

This page discusses minor bodies in the solar system, which include small, irregularly shaped objects like asteroids, comets, and meteoroids, as well as Kuiper Belt and Oort Cloud Objects.

Other areas of the Solar System also encompass small bodies in smaller concentrations. These include the near-Earth asteroids, centaurs, comets, and scattered disc objects.

Small Solar System Bodies are remnants of the formation of the planetary system, including comets, asteroids, and TNOs, which are attractive targets for sample return missions due to their low-gravity ...

Beside the eight planets and their satellites there are many smaller size bodies in the solar system. These include four families: asteroids, dwarf planets, comets and meteors/meteorites. ...

Small solar system bodies include things like comets, asteroids, moons, and the icy objects in the Kuiper Belt and the Oort cloud.

The small bodies populate the solar system in vast numbers and include the mostly rocky asteroids, or minor planets, the predominantly icy comets, and the fragments of such bodies--commonly called ...

What are the physical properties of small bodies in the Solar System (comets, asteroids, Kuiper Belt Objects, Centaurs, rings, and satellites) and how are they interrelated?
